

## New guidelines detail use of ‘infant-safe’ peanut to prevent allergy

January 5, 2017

With a potentially huge public health impact, new AAP-endorsed guidelines outline a new approach that promises to reduce the risk of peanut allergy.

Estimated to affect 1%-2% of children, peanut allergy often is severe and lifelong. The new guidelines recommend early introduction of peanut protein for infants who are at increased risk of developing the allergy. They caution, however, that peanuts and peanut butter are choking hazards, and advise on forms that are safe for infants such as peanut butter smoothed into pureed fruits or vegetables.

*Addendum Guidelines for the Prevention of Peanut Allergy in the United States: Report of the National Institute of Allergy and Infectious Diseases-Sponsored Expert Panel* is available at [http://www.annallergy.org/article/S1081-1206\(16\)31164-4/fulltext](http://www.annallergy.org/article/S1081-1206(16)31164-4/fulltext) and is co-published today in the *Journal of Allergy and Clinical Immunology* and other journals.

The guidelines are based primarily on the results of the landmark Learning Early About Peanut (LEAP) trial (Du Toit G, et al. *N Engl J Med.* 2015;372:803-813). The study randomized 640 infants from 4-11 months of age with severe eczema and/or egg allergy to ingest or avoid peanut until 60 months of age. The study excluded infants with large positive skin prick tests (SPTs) to peanut, assuming they already were allergic, and stratified the enrolled infants as having no peanut SPT wheal or having one that was 1-4 millimeters in diameter.

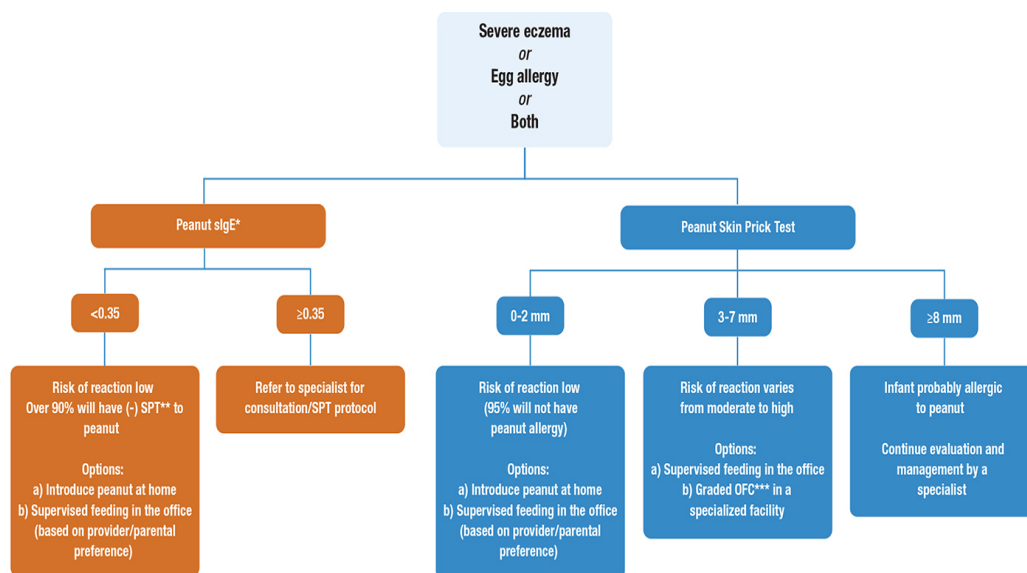

The results showed that in the negative SPT group, the prevalence of peanut allergy at age 5 was 13.7% in the avoidance group vs. 1.9% in the consumption group ( $p<0.001$ ; 86.1% relative risk reduction). Among those in the SPT positive group, the prevalence of peanut allergy was 35.3% in the avoidance group and 10.6% in the consumption group ( $p=0.004$ ; 70% relative risk reduction).

### **New recommendations based on risk**

Three new guidelines in the addendum characterize infants based on clinical features reflecting the risk of having or developing peanut allergy and provide recommendations accordingly.

**Guideline #1** recommends that the highest risk infants — those with severe eczema and/or egg allergy (see definitions below) — be introduced to peanut as early as 4-6 months of age, following successful feeding of other solid food(s) to ensure the infant is developmentally ready.

Allergy testing is strongly advised prior to peanut introduction for this group. The preferred test is the SPT, but the guideline also allows for blood testing for peanut-specific IgE (sIgE), which is more widely available (see figure, right-click to enlarge). Allergy tests for multiple foods are not recommended because of their poor positive predictive value.

\* To minimize a delay in peanut introduction for children who may test negative, testing for peanut-specific IgE may be the preferred initial approach in certain health care settings. Food allergen panel testing or the addition of sIgE testing for foods other than peanut is not recommended due to poor positive predictive value.

\*\* skin prick test

\*\*\* oral food challenge

The guideline also recommends home or physician-supervised feeding or exclusion of peanut based on the test results. If a blood test is used to screen and is positive to peanut (sIgE  $\geq 0.35$  kU<sub>A</sub>/L), referral to a specialist with training and experience to perform and interpret the peanut SPT and to safely perform medically supervised feeding tests is advised. The guideline discusses the manner of peanut introduction according to the test results, whether at home or under physician supervision.

Additionally, the amount to feed weekly is discussed. Based on what was done in the LEAP study, 6-7 grams of peanut protein is given over three or more feedings per week. The LEAP study had infants eat this amount to age 5 years. In studies following up on the LEAP trial, this approach resulted in durable protection, was safe, did not affect duration or frequency of breastfeeding, and did not influence growth or nutrition.

**Guideline #2** suggests that infants with mild to moderate eczema, a group also at increased risk of peanut allergy, should be introduced to peanut “around 6 months of age, in accordance with family preferences and cultural practices, to reduce the risk of peanut allergy.” These infants may have peanut introduced at home following successful ingestion of other solid food(s) without an in-office evaluation, although an evaluation can be considered.

**Guideline #3** addresses infants without eczema or food allergy who are not at increased risk, suggesting that peanut be introduced “freely” into the diet together with other solid foods and in

accordance with family preferences and cultural practices.

### **Guidance evolves**

Purposeful early feeding of peanut is a reversal from the 2000 AAP recommendations that suggested high-risk infants avoid peanut to age 3 years. The avoidance advice was rescinded in the 2008 AAP clinical report *Effects of Early Nutritional Interventions on the Development of Atopic Disease in Infants and Children: The Role of Maternal Dietary Restriction, Breastfeeding, Timing of Introduction of Complementary Foods, and Hydrolyzed Formulas* (Pediatrics. 2008;121:183-191; <http://bit.ly/2hDuw1f>), which concluded: “Although solid foods should not be introduced before 4 to 6 months of age, there is no current convincing evidence that delaying their introduction beyond this period has a significant protective effect ...”

The new guidelines go further by promoting early ingestion for the highest risk infants. Evaluation and peanut introduction for this highest risk group at 4-6 months is conveniently timed with routine pediatric health care office visits, allowing for identification of infants at risk and discussion of the approach. Additionally, it is less likely for younger infants to have positive allergy tests to peanut. However, the guideline emphasizes that if the 4- to 6-month time period is missed for any reason, peanut should be introduced to infants older than 6 months as they also are anticipated to benefit (the LEAP study included infants 4 up to 11 months of age).

The addendum guidelines represent an update to the 2010 comprehensive food allergy guidelines published by a National Institute of Allergy and Infectious Diseases (NIAID)-sponsored expert panel (<http://bit.ly/2gTLoSF>). They reflect the work of a coordinating committee and expert panel representing 26 professional organizations, including the Academy, advocacy groups and federal agencies, which evaluated a literature review prepared by the NIAID.

### **Definitions in the addendum guidelines**

**Severe eczema** is defined as persistent or frequently recurring eczema with typical morphology and distribution, assessed as severe by a health care provider and requiring frequent need for prescription-strength topical corticosteroids, calcineurin inhibitors or other anti-inflammatory agents despite appropriate use of emollients.

**Egg allergy** is defined as a history of an allergic reaction to egg and a skin prick test wheal diameter of  $\geq 3$  millimeters with egg white extract or a positive oral egg food challenge.
